

Predicted vs observed projection-vs-distance from HP

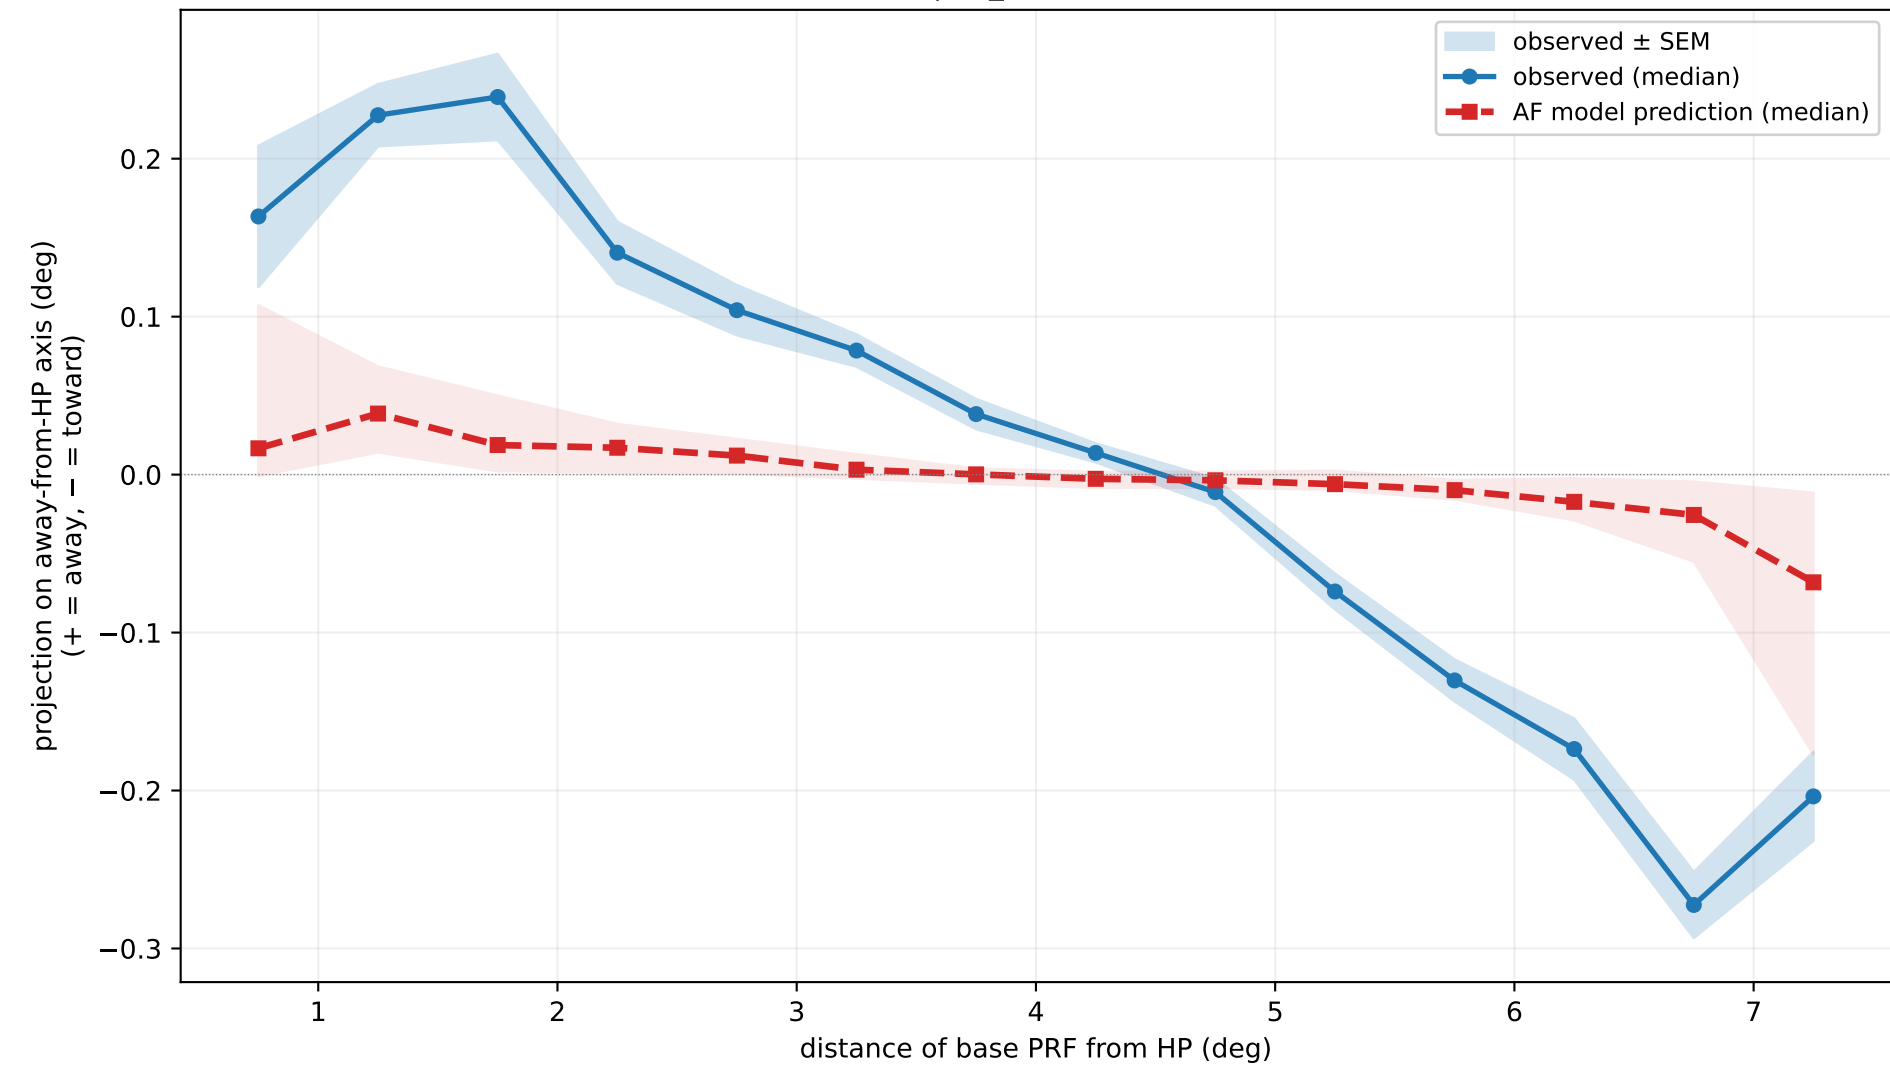

TSV : notes/predict_shifts_cluster.tsv

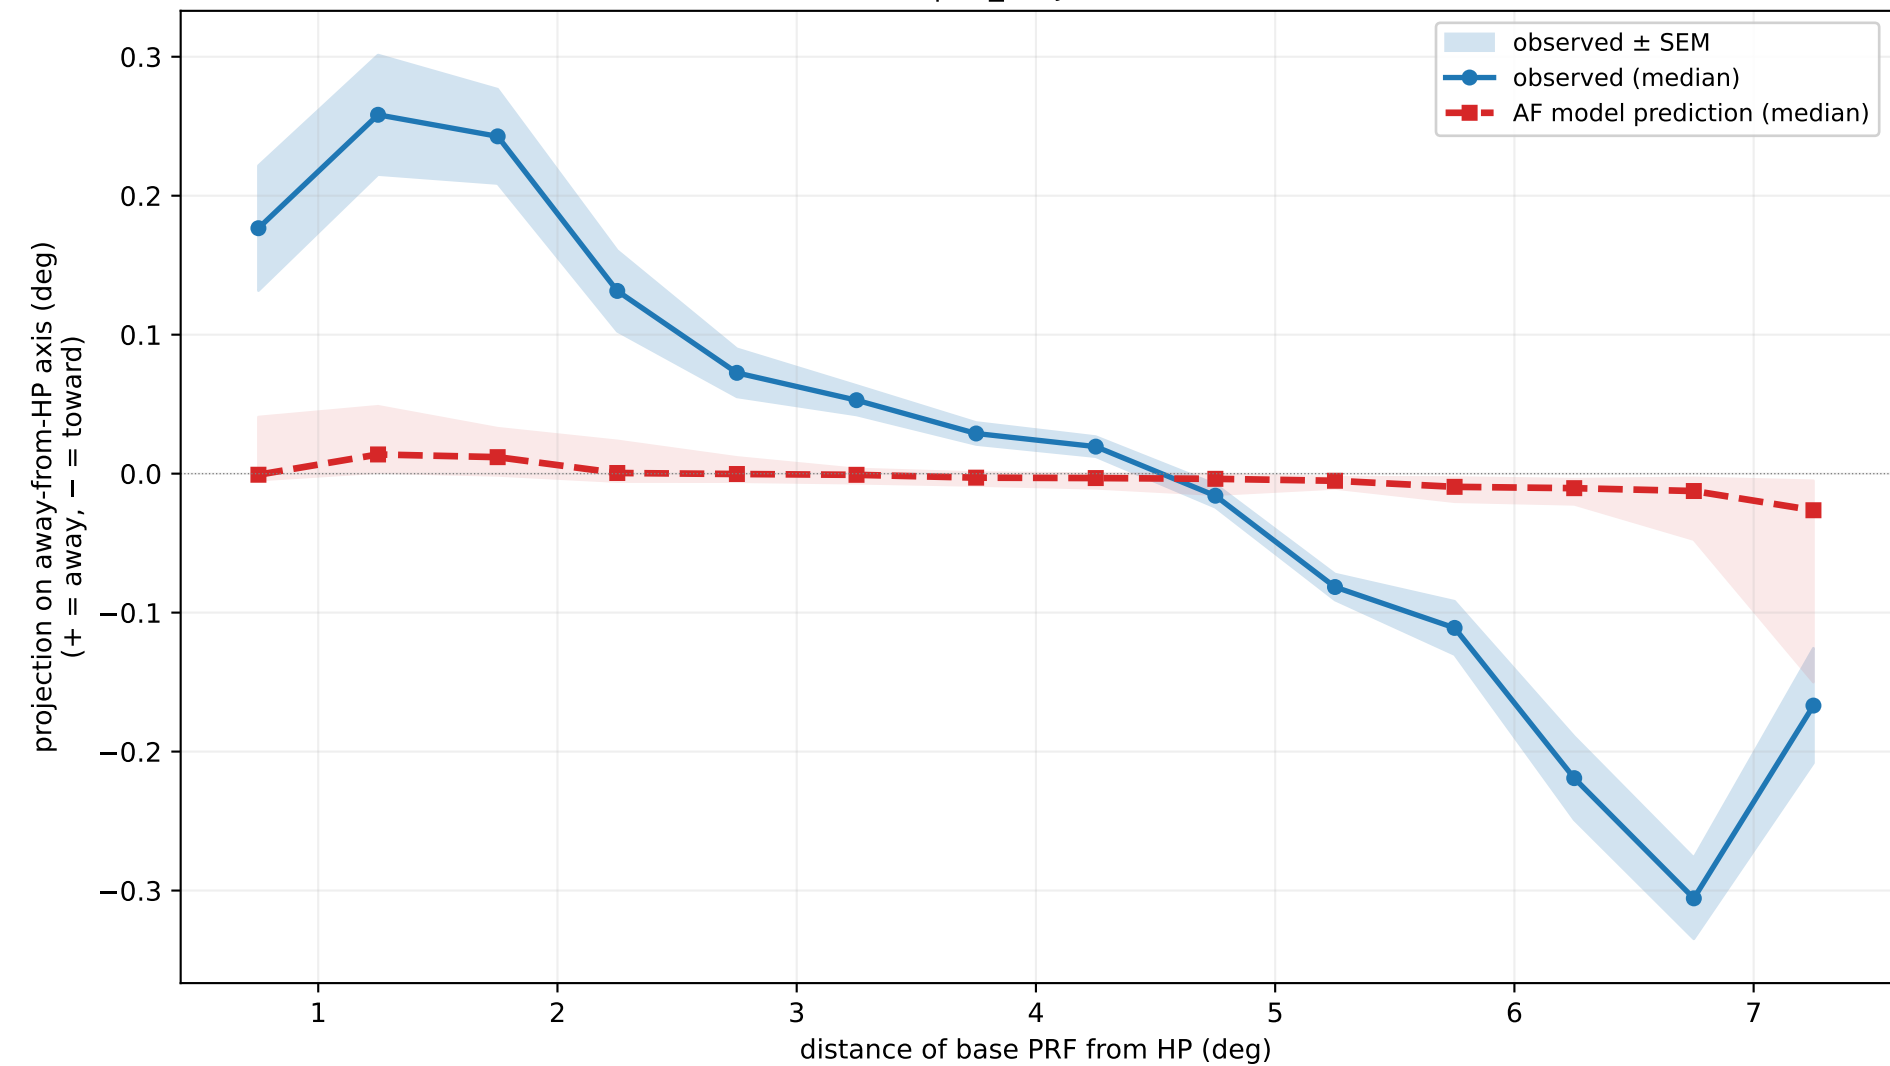

Bins : 0.5° wide, 0.0° to 8.0°

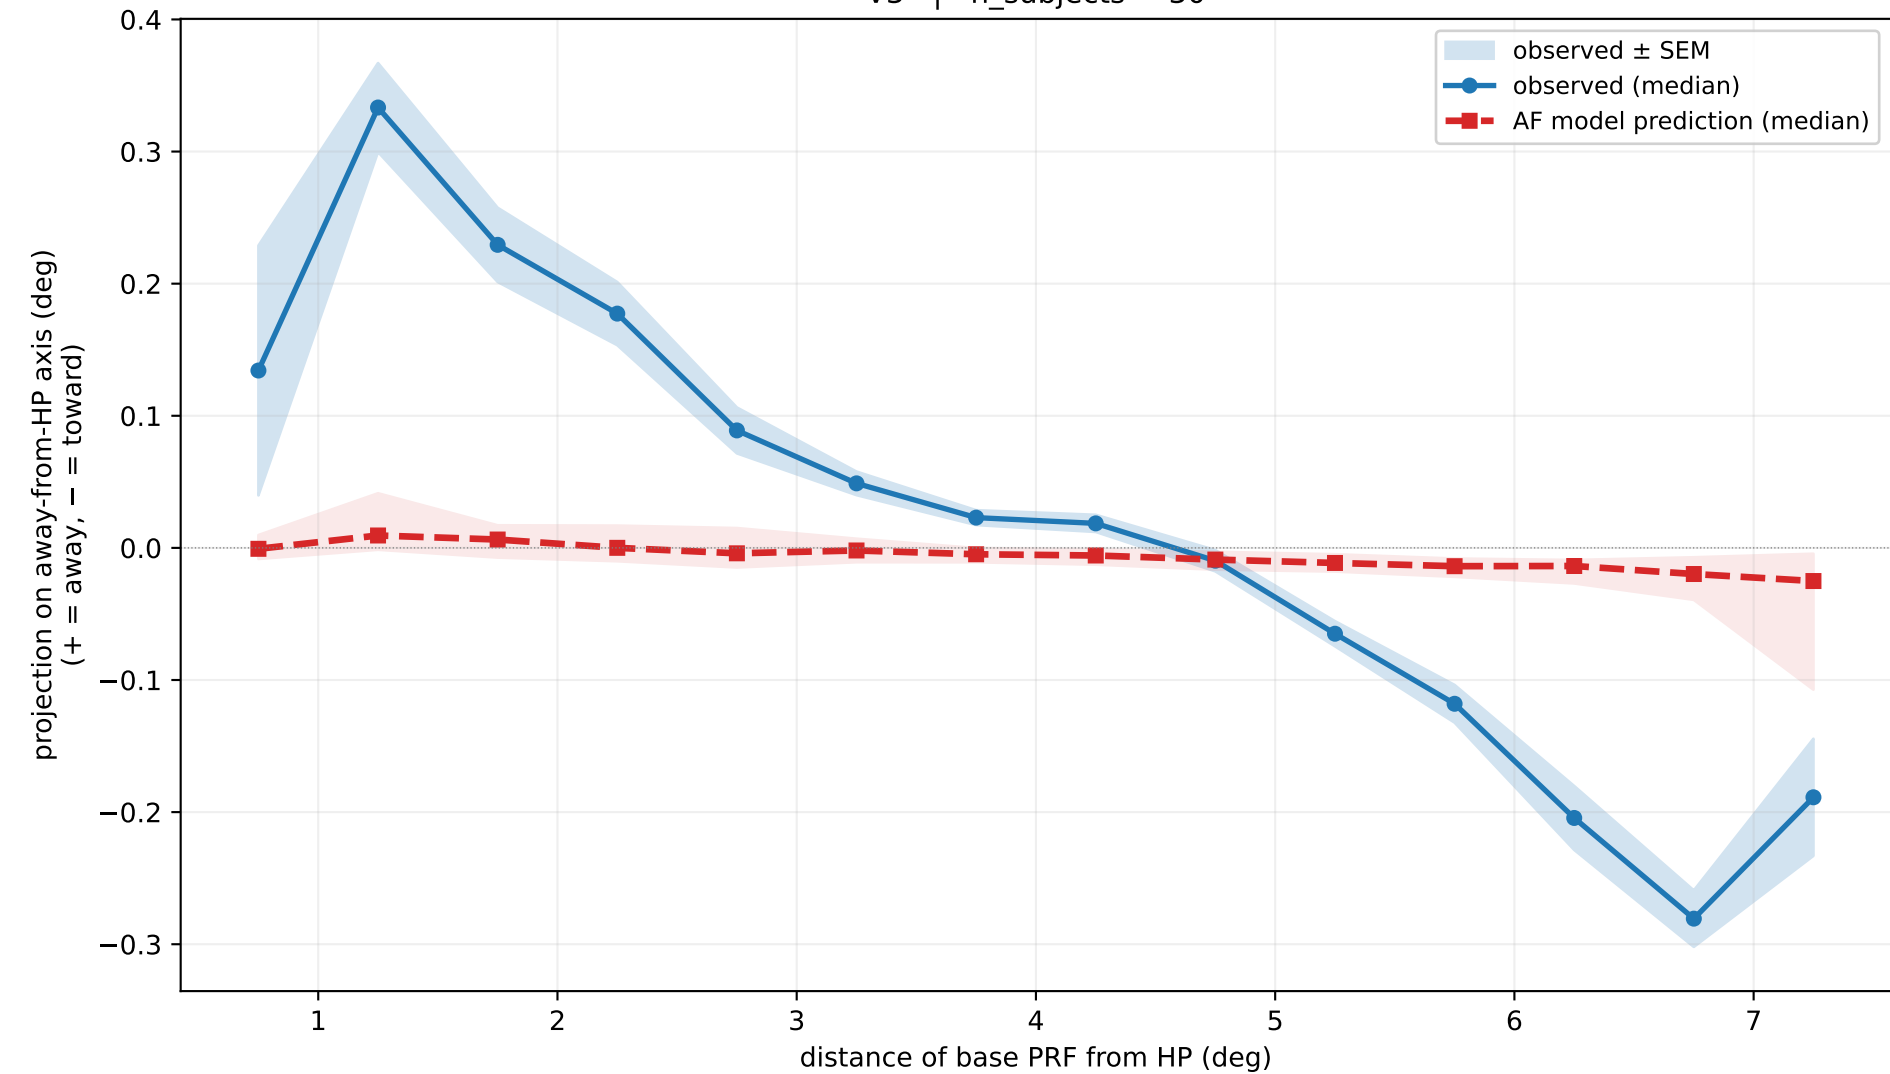

Per ROI:

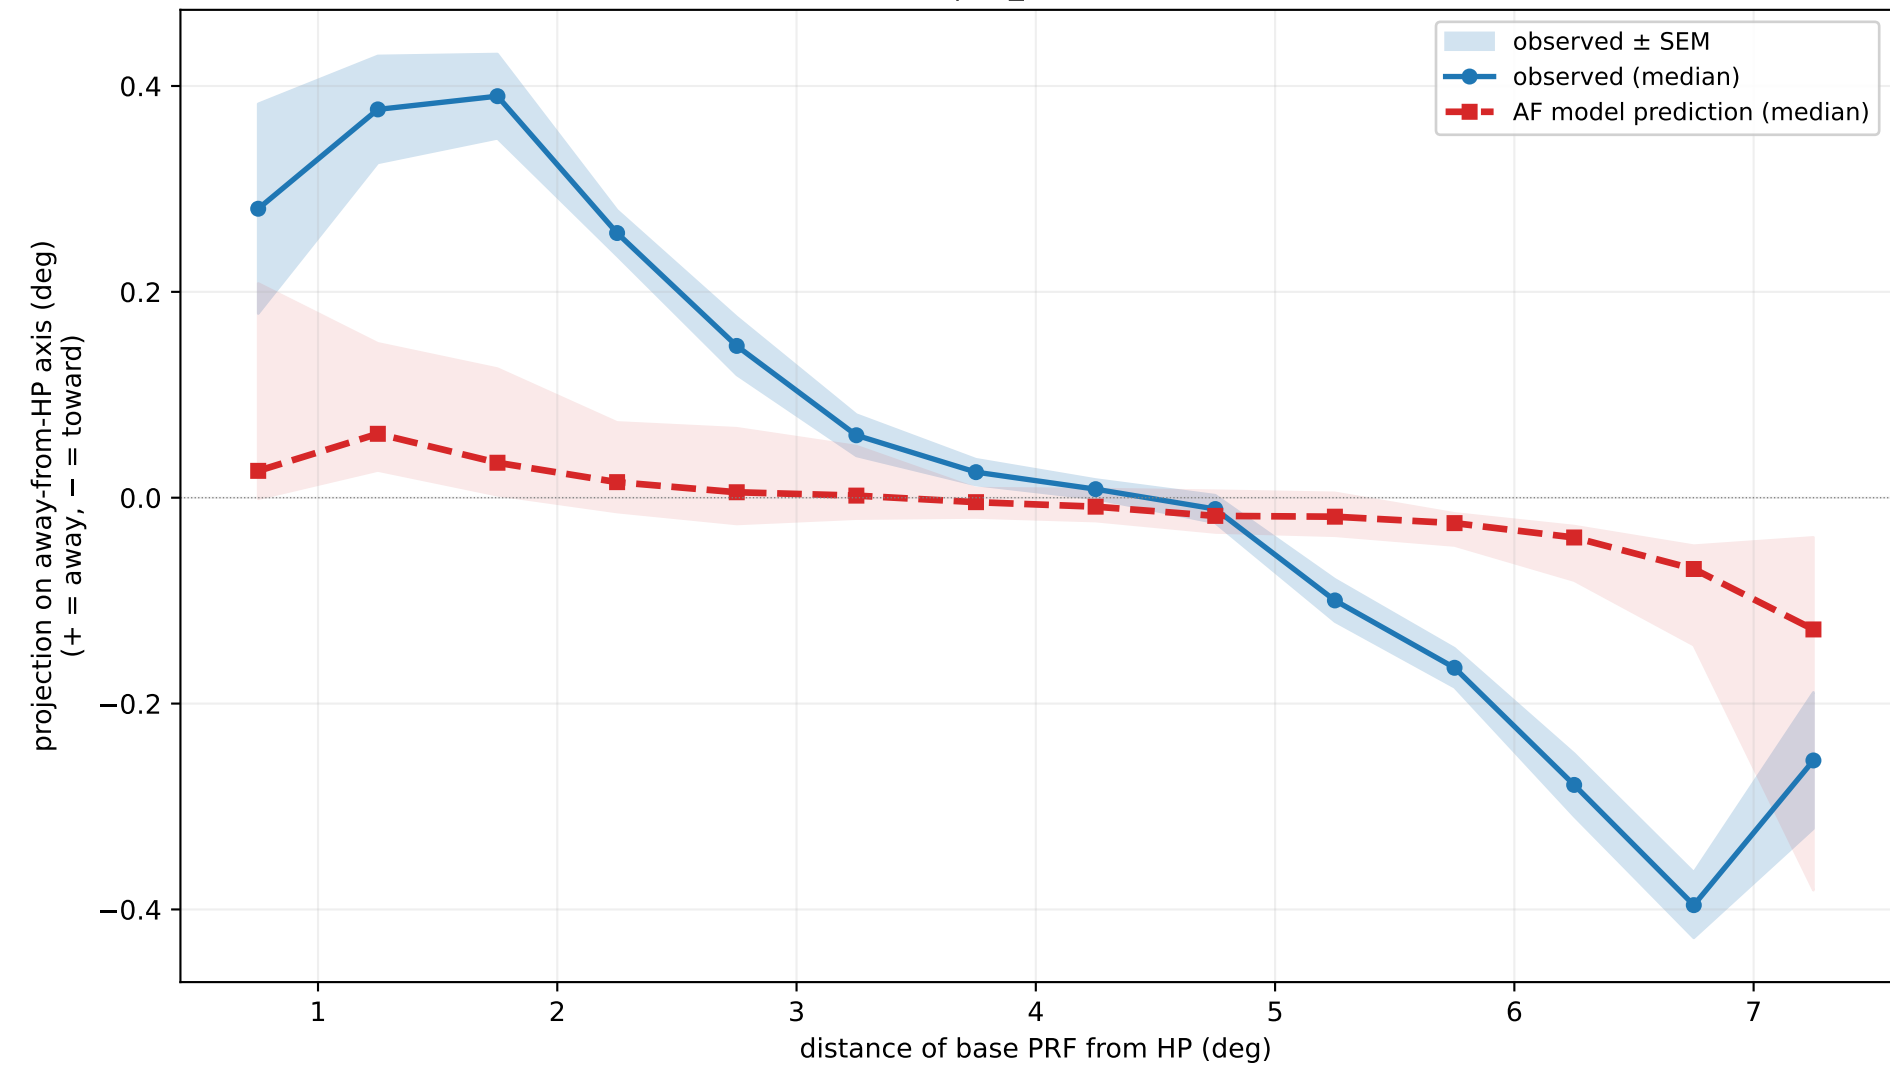

- For every (subject × condition × voxel) row inside the bar aperture (radius 3.17°), compute distance from HP.
- Per-subject mean of proj_obs and proj_pred per bin.
- Plot the across-subject MEDIAN for both, with ± 1 SEM band on the observed curve.

If the predicted curve (red dashed) tracks the observed curve (blue), the joint AF+PRF fit recovers the empirical voxelwise shift pattern.

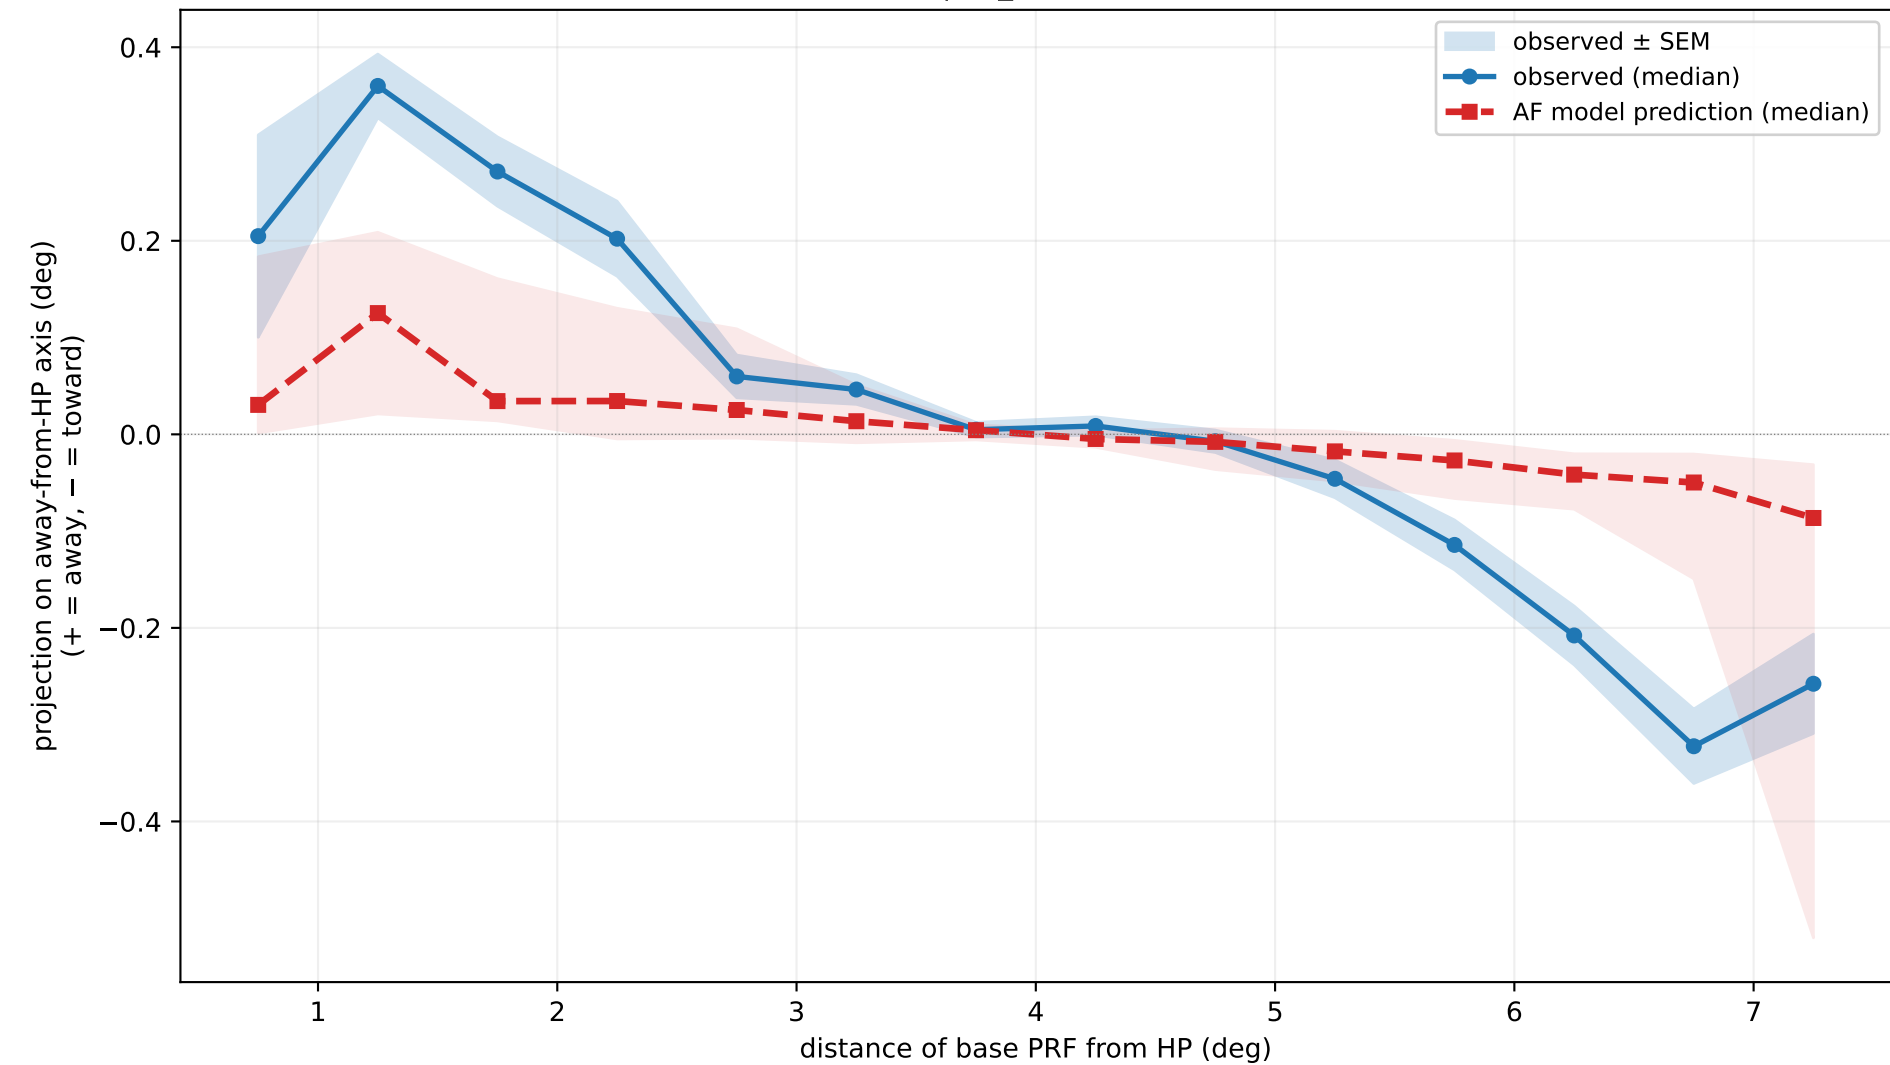

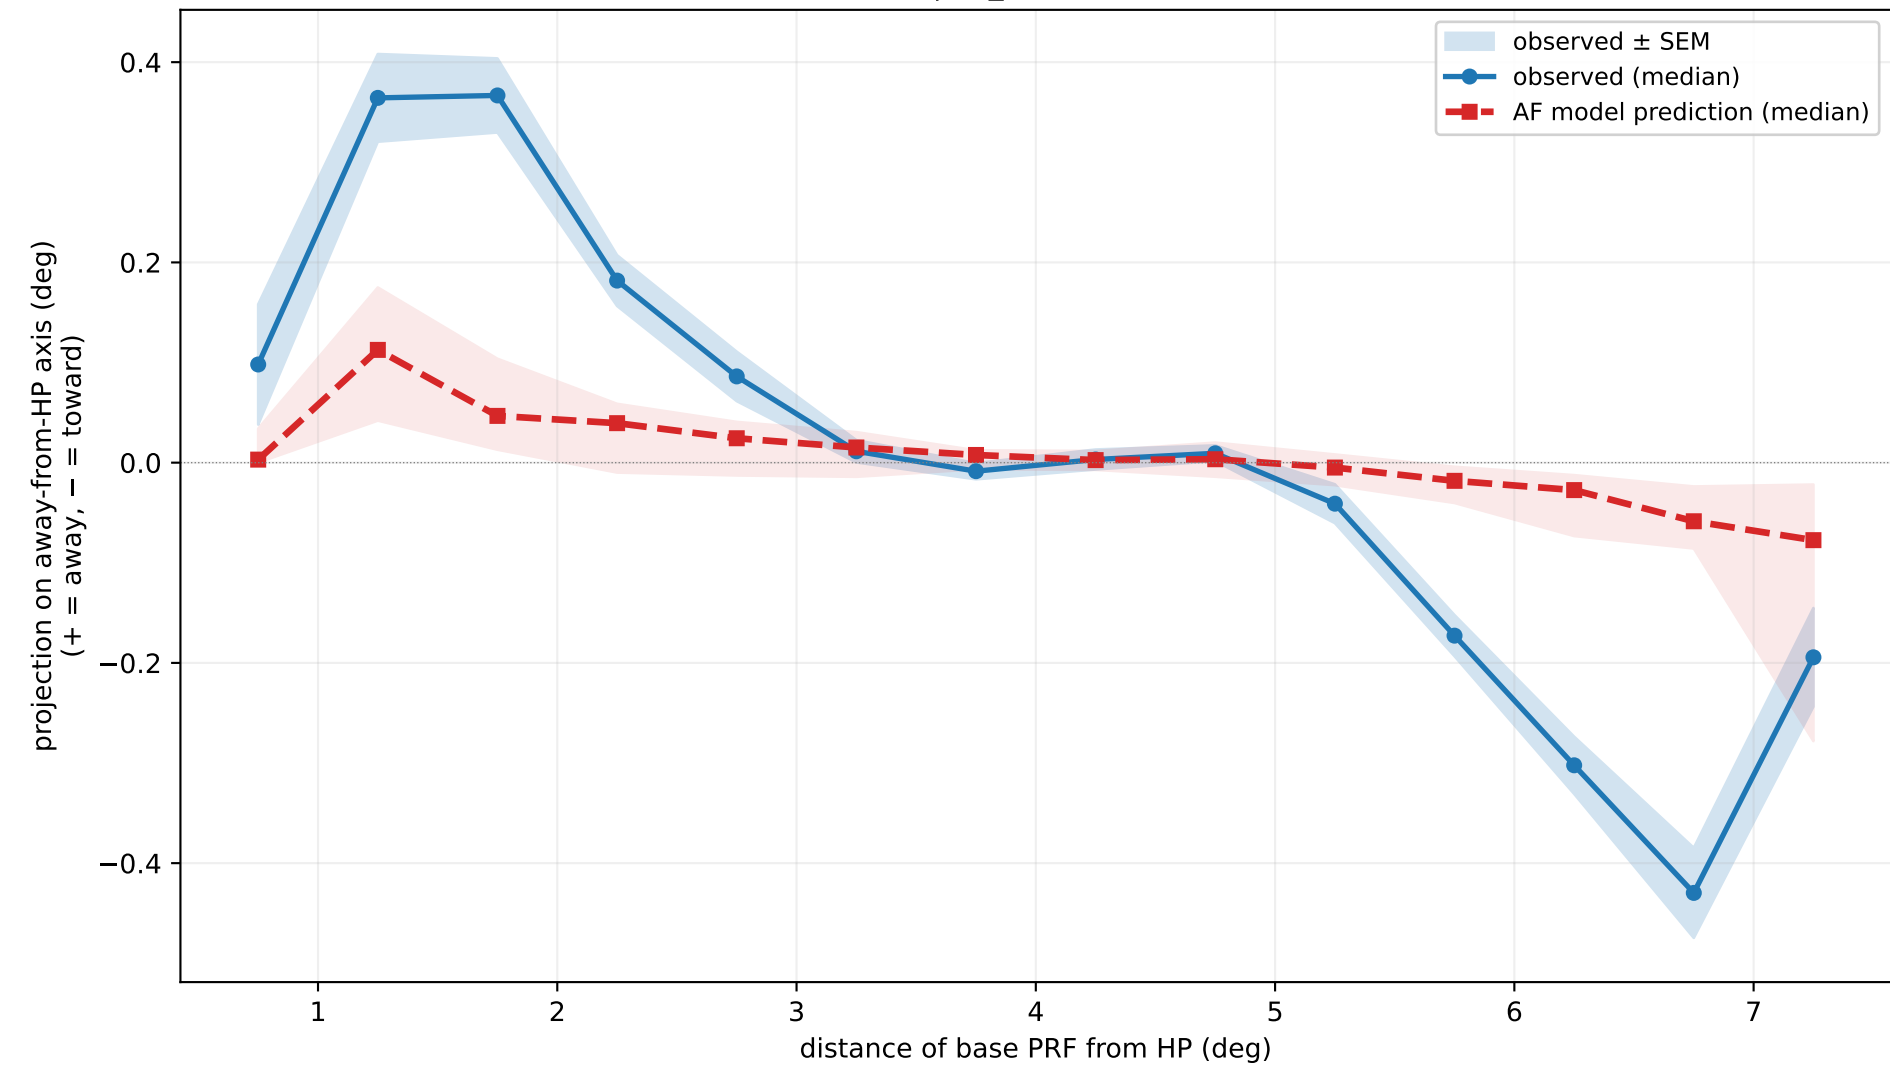

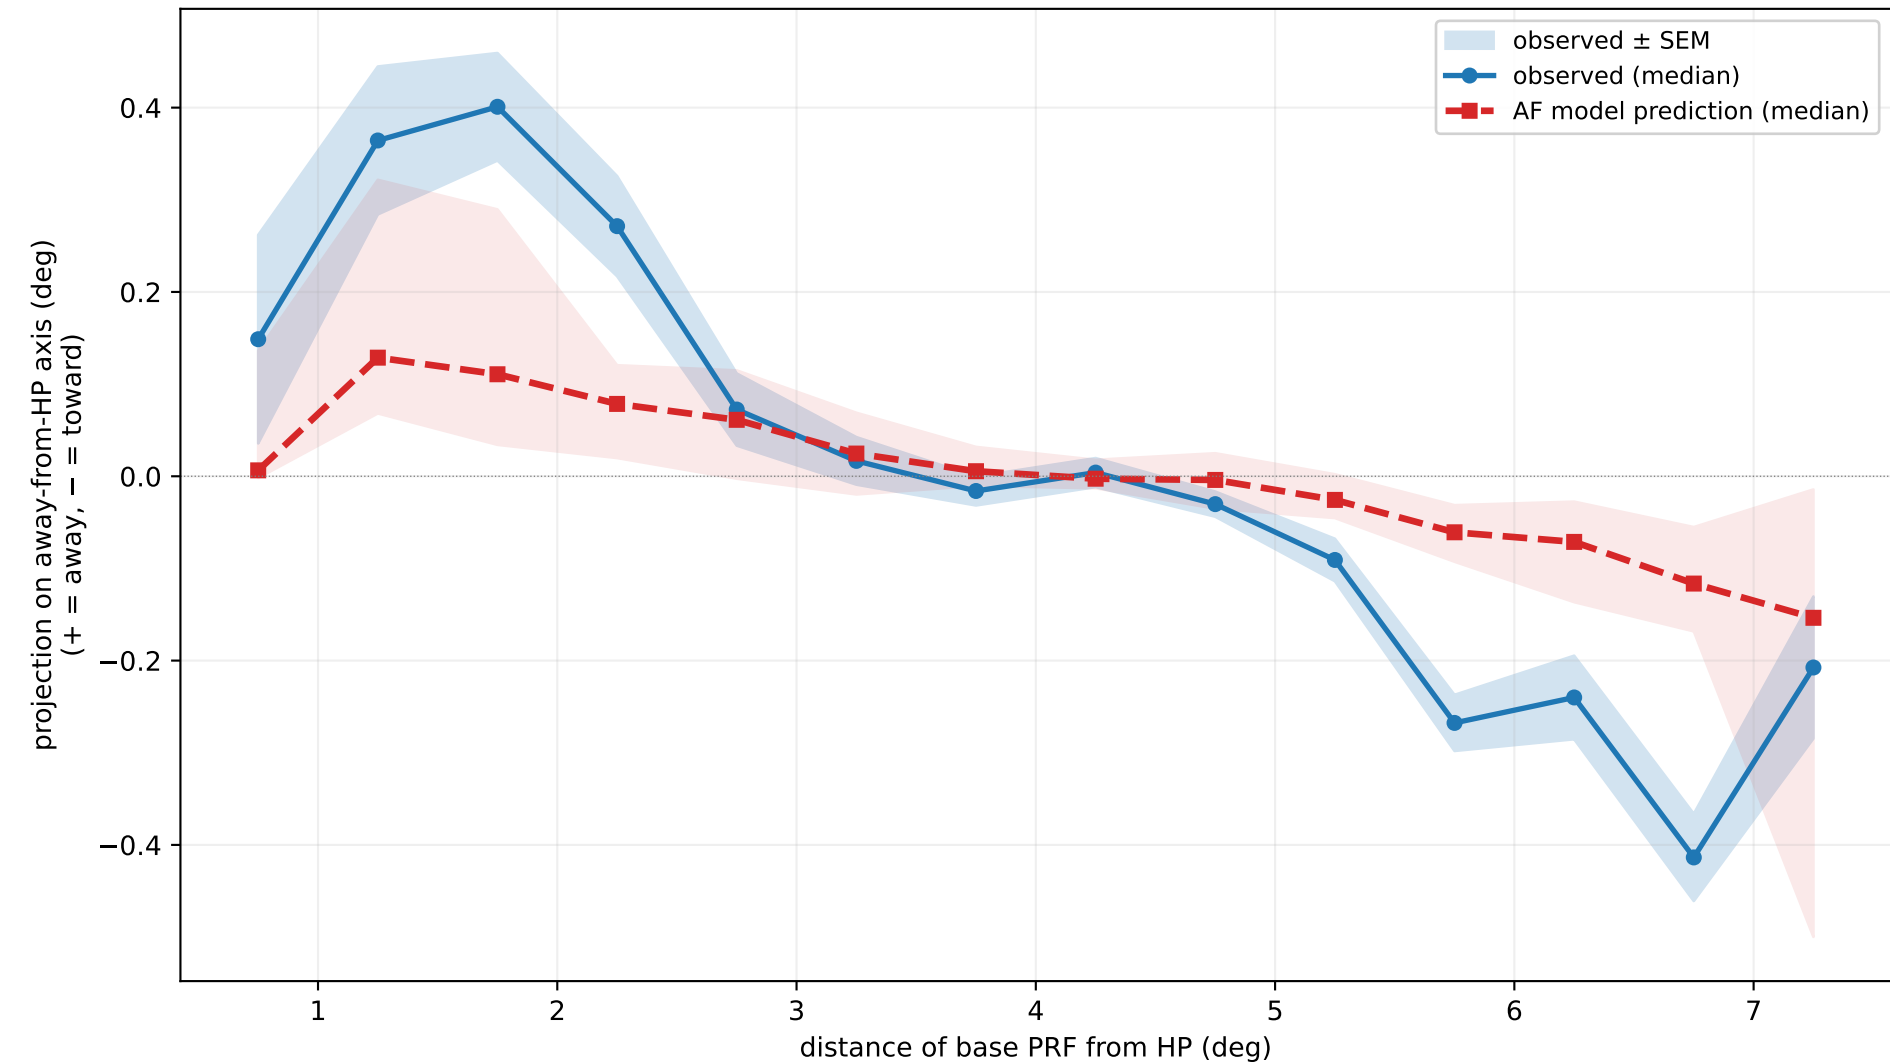

hV4 | n_subjects = 30

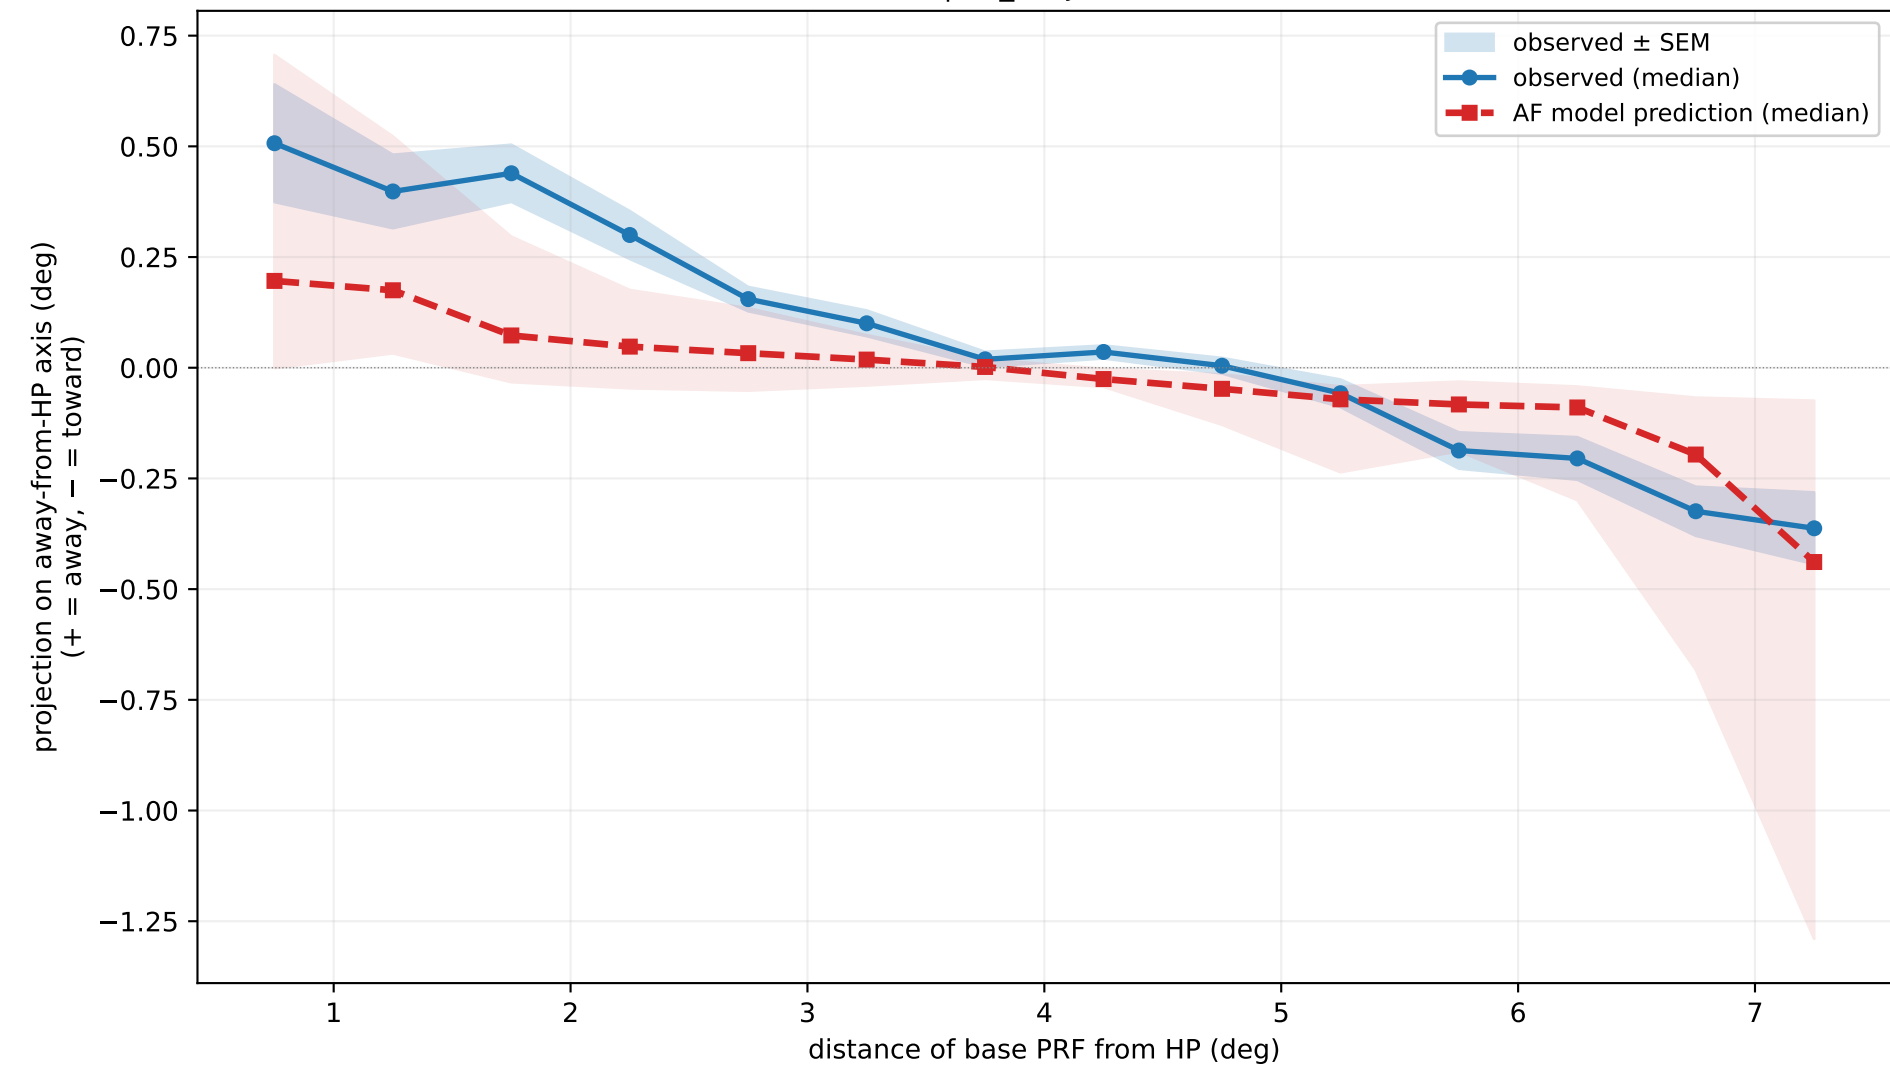

LO | n_subjects = 30

VO | n_subjects = 30

Per-ROI overview: model prediction (red) vs observed (blue) projection-vs-distance

projection on away-from-HP axis (deg)
