

Rotated-frame projection heatmaps per ROI

Source TSV : notes/predict_shifts_cluster.tsv
Total rows : 618,148
Subjects : 30

How to read each ROI page:

- Every (subject × condition × voxel) row rotated so HP is at canonical (0, +4°) – ★ in each panel.
- Per-bin MEDIAN projection of the shift on the AWAY-FROM-HP axis (= -y in the canonical frame).
 - red = away from HP (suppression direction)
 - blue = toward HP (attraction direction)
- Bins with < 30 observations dropped (white).
- PRED and OBS share a colorscale; residual has its own.
- Outside the bar aperture (radius 3.17°) is not constrained by the experiment – bins outside the dashed circle are still shown when they have data, but read with caution.

Why this is the right plot:

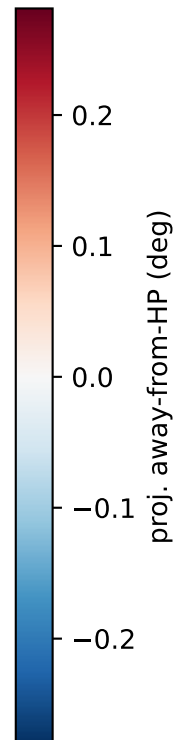

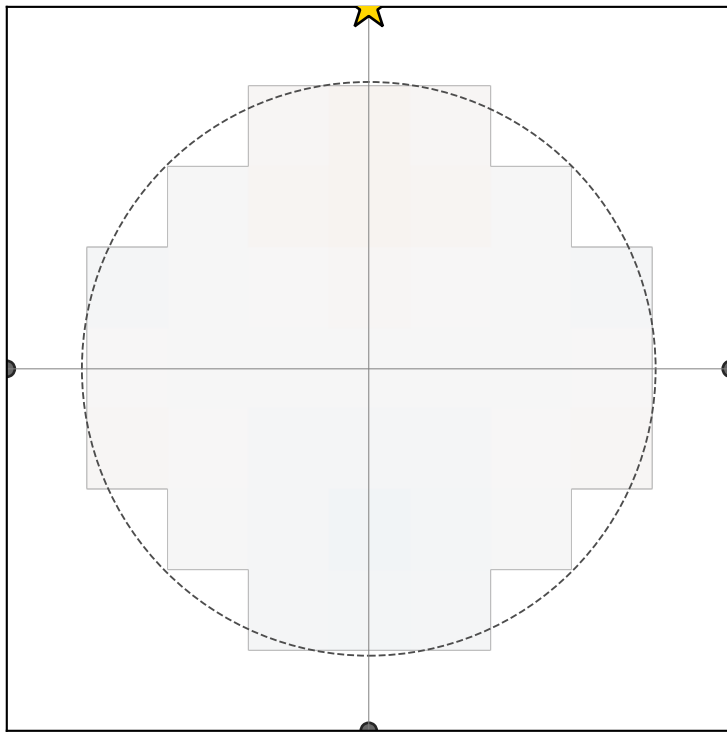

- 2D analog of proj_distance_curves.pdf (which collapses to 1D distance and so cannot show the spatial structure of where attention is acting).
- Heatmap not arrows – robust to outlier voxels that blow up bin medians of vector magnitude.

Caveat – Jensen-style noise bias:

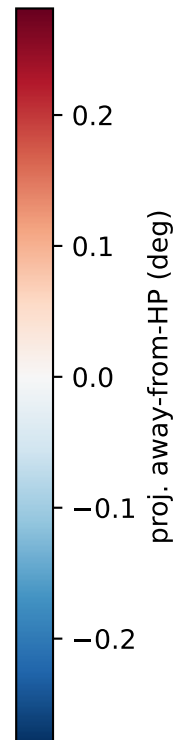

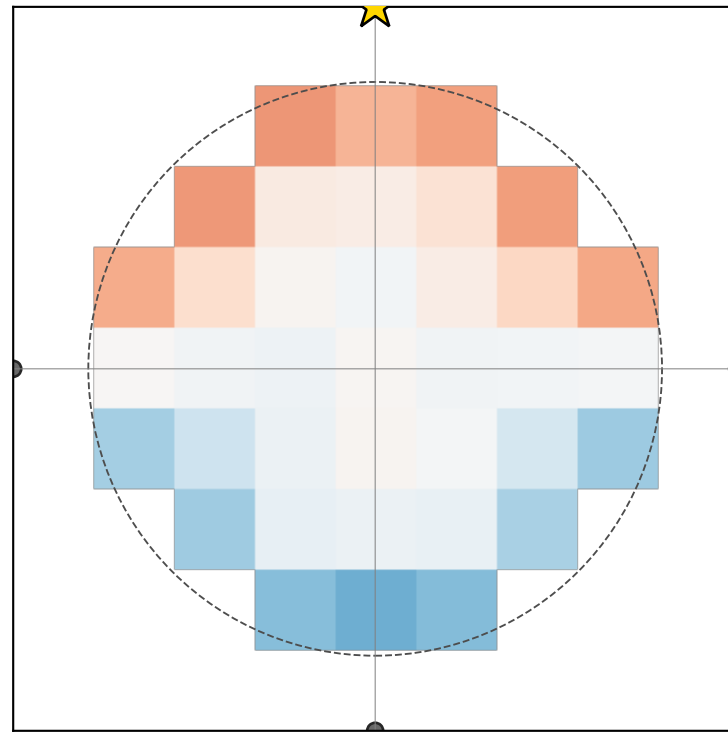

- base_xy and obs_xy come from independent fits, so noise on base partially leaks into the binning. Voxels that happen to land in the small-distance bin tend to have base_xy fluctuated TOWARD HP; the obs_xy estimate (independent noise) regresses toward truth → AWAY from HP. So the OBSERVED panel can show a near-HP "away" stripe even with zero true effect. The PRED panel is deterministic given base_xy and has NO such bias.
- Read the PATTERN match (peak location, decay shape), not the magnitude difference, as the test of whether the model captures the data.

GROUP (all 30 subjects)
