

Even PRFs only sensitive to the bar (not distractors) are affected
sub-28 V3AB params: $g_{HP}=-0.77$, $g_{LP}=+1.02$, $\sigma_{AF}=1.09^\circ$ (real fit)

A. Modulation field $M(g)$

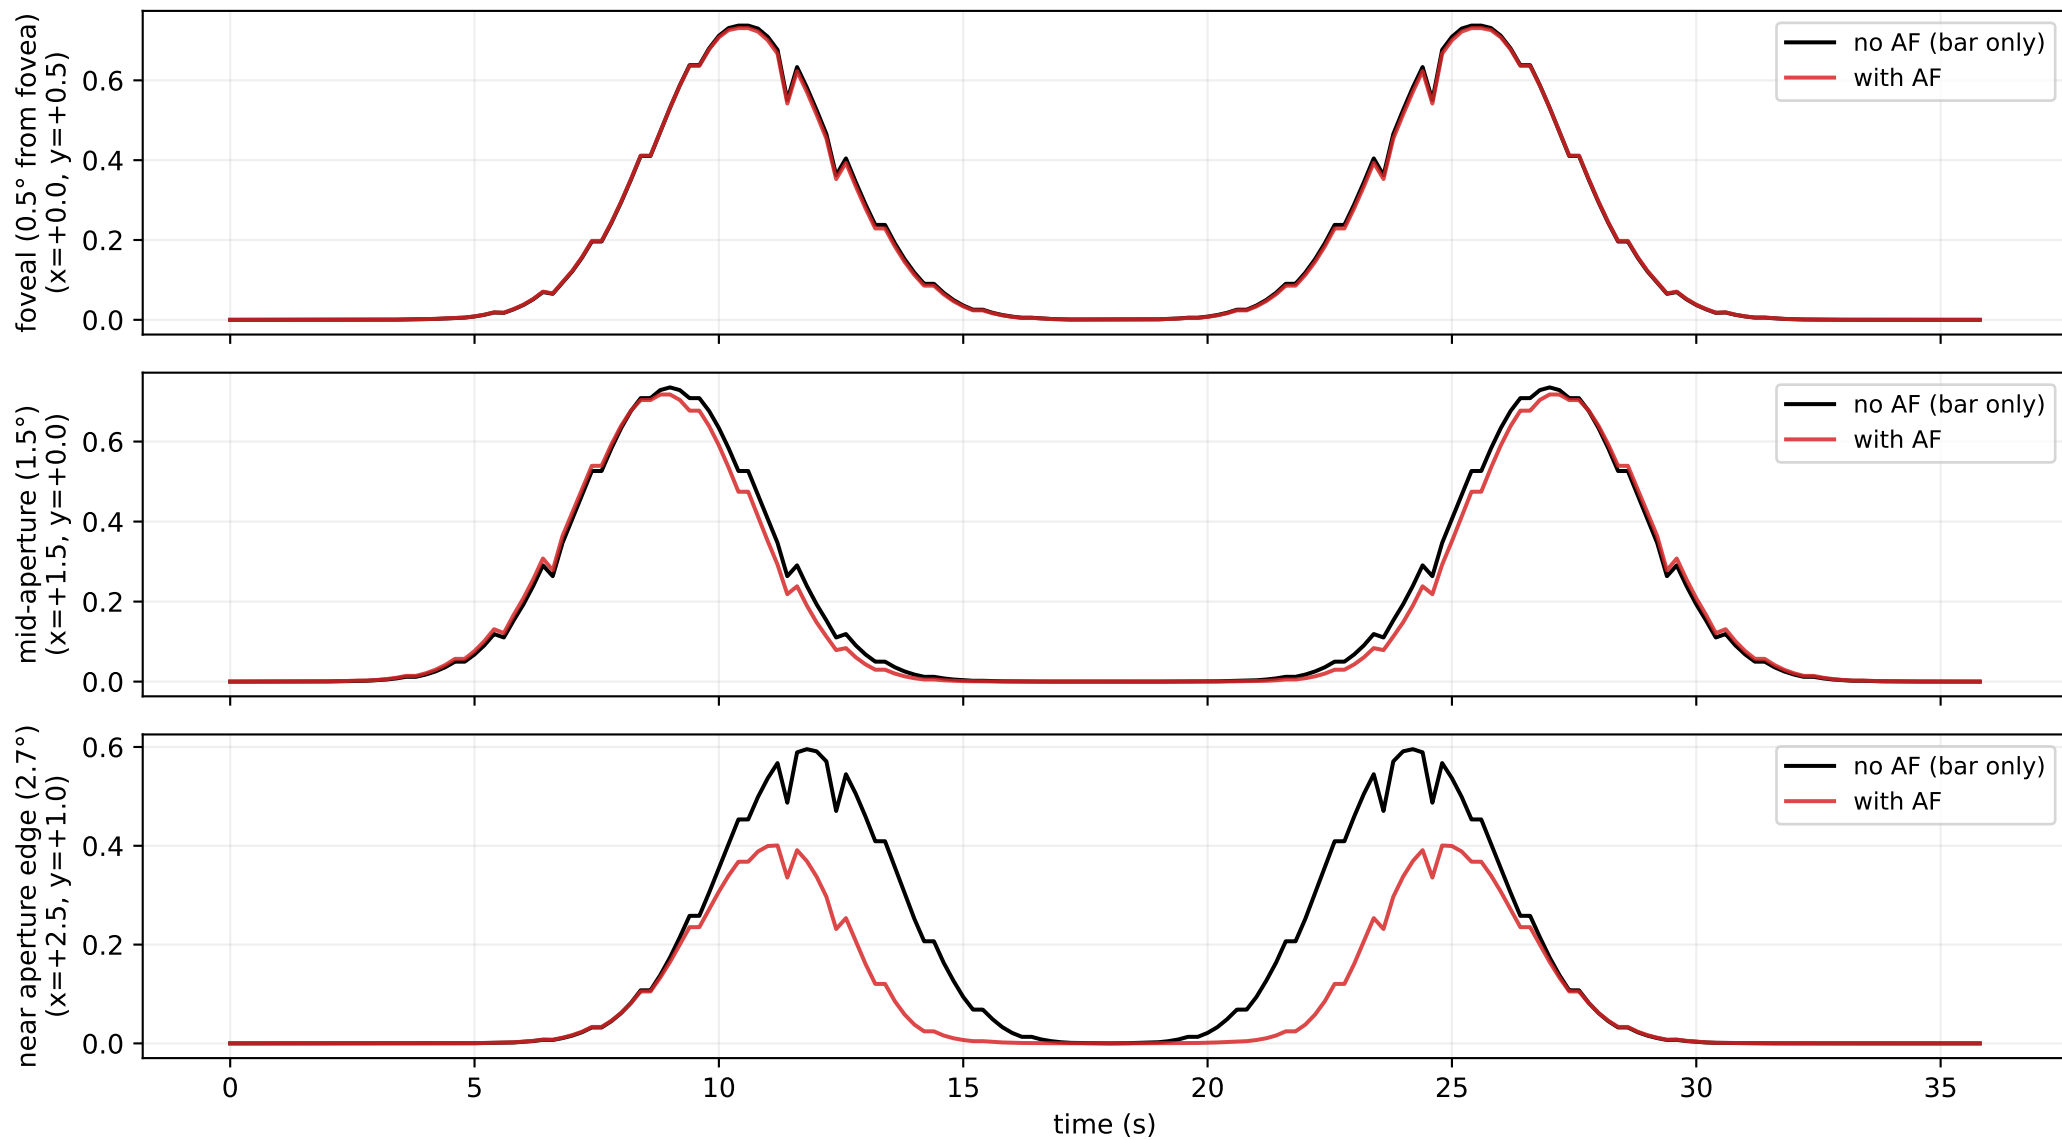

AF Gaussian tails clearly extend INTO the aperture

B. AF-induced response modulation per PRF position
Magnitude > 0 throughout aperture (fovea included)

**C. Predicted bar-driven BOLD response per PRF position
with vs without AF — even foveal voxels show modulation when bar overlaps regions where $M(g) \neq 1$**

D. AF effect magnitude vs PRF distance from HP
Effect persists across the whole aperture (left of dashed line)
and even into far-from-aperture territory.
